#### Abstract

Side friction factors are all those actions related to the activities taking place by the sides of the road and sometimes within the road, which interfere with the traffic flow on the travelled way. They include but not limited to pedestrians, bicycles, non-motorized vehicles, parked and stopping vehicles. These factors are normally very frequent in densely populated areas in developing countries, while they are random and sparse in developed countries making it of less interest for research and consequently there is comparatively little literature about them. The objective of this thesis is to analyze the effect of these factors on capacity of urban roads. The present study is mainly focused on individual effect of the friction factors like pedestrians crossing the road on capacity of urban roads. Data on two sections of 4-lane divided road were collected in Hyderabad with pedestrian cross flow. These are taken as the base sections. Three basic parameters of traffic speed, volume and density are used for estimation of traffic carrying capacity of a road. For determination of speed-volume relationship in heterogeneous traffic condition, the volume calculated by total vehicles recorded for each counting period were converted into equivalent number of PCUs. Mean stream speed or weighted space mean speed is calculated and used in the present study. The present study demonstrates that mix traffic stream can be converted in to an homogeneous equivalent of passenger cars by multiplying the total traffic volume (in veh/hr) by a stream equivalency factor (K). It will avoid the problem of estimation of PCU values for individual vehicle categories in the traffic stream. The stream equivalency factor ( K ) will depend on traffic composition and a regression equation is developed in this study to estimate K -value on urban roads.

Keywords: Side friction factors; Capacity; Pedestrians; Urban roads

## 1. Introduction

Urban areas in most of the developing countries are facing major challenges in traffic management and control and India is no exception. It has witnessed a rapid growth in economy in recent years, resulting in vehicle ownership levels growing at a faster rate. The total road length in India including highways, rural roads, urban roads, project roads as on $31 \mathrm{~s}^{`}$ March 2008 was $42,36,429 \mathrm{~km}$. The total length of urban roads in the country as on 31 st March 2004 was $3,01,3$ 10 km which increased to $3,04,327 \mathrm{~km}$ by March 2008 (MORT\&H, 2010) indicating a growth of about 1 percent. Capacity analysis is fundamental to planning, design and operation of roads. Among other things, it provides the basis for determining the number of traffic lanes to be provided for different road sections having regard to volume, composition, and other parameters of traffic. Alternatively, for existing road network, the capacity analysis provides a means of assessing the traffic carrying ability of the number of traffic lanes provided for a given road link under the prevailing roadway and traffic conditions. Capacity standards can therefore help in rational evaluation of the investments needed for further road construction and improvements.

[^0]Indian urban roads are typically categorized with the mixed nature of traffic. Mixed traffic represents the conglomeration of different vehicles those having much variation in their operating speeds, fleet size and difference in maneuvering abilities. Speed varies from $3.5 \mathrm{~km} / \mathrm{hr}$ in case of hand carts to $60 \mathrm{~km} / \mathrm{hr}$ or more for passenger cars. Presence of slow-moving vehicles in traffic stream results in reduced average speed of the traffic stream. Consequently, this speed reduction results in frequent stoppages, acceleration and deceleration and movement in lower gear increases the operational cost exorbitantly besides giving rise in environmental pollution. The conflict, confusion and the irritation caused by mixed traffic with lane indiscipline result in a large number of accidents. This leads to frequent congestion on urban roads.

## 2. Data extraction

The video recorded data were used to extract the information on classified traffic volume count and speed of individual vehicles. All vehicles are divided in to 4 categories and their average physical dimensions are shown in Table-3.2.

Table 1 Vehicle Categories and their Average Dimensions

| S.NO | Class of vehicle | Average dimensions |  | Projected rectangular plan area (m²) |
| :--- | :--- | :--- | :--- | :--- |
|  |  | Length(m) | Width(m) |  |
| 1 | Standard car | 3.72 | 1.44 | 5.39 |
| 2 | Bus/truck | 10.10 | 2.43 | 24.74 |
| 3 | Three-wheeler | 3.20 | 1.4 | 4.48 |
| 4 | Two-wheeler | 1.87 | 0.64 | 1.2 |

The standard car is taken as a passenger car having length 3.98 m , width 1.54 m and engine power of 1405 cc . Tata Indigo, Indica, Hyundai Getz etc. were considered as standard cars. The classified volume count of all vehicles passing through a specified point, say first line of the trap, during a fixed period of 5 minute provided the measurement for composition and flow. The average time taken by each category of vehicle to cover the trap length was recorded using a digital stop watch of 0.01 second accuracy. The precaution was taken to consider only those periods during which there was continuous flow of the vehicles with representation of each category. For the purpose of speed measurement of a vehicle type, 6-8 vehicles of that category were randomly picked up during the flow and average of speeds was taken for the analysis.

## 3. Analysis of data and result

The data on classified volume count and average speed of each vehicle category on the selected mid-block were extracted from the video film in the manner. The data were analyzed to obtain the average speed of the vehicles on traffic stream, hourly traffic volume and speed ( $\mathrm{m} / \mathrm{s}$ ) of each type of vehicle on different mid-block sections. From the video films obtained, the speed of individual vehicles in the normal traffic flow and the classified volume was estimated for `of the vehicles on traffic stream at different sections is given in Table.

### 3.1. Speed

Speed is considered as a quality measurement of travel as the drivers and passengers will be concerned more about the speed of the journey than the design aspects of the traffic. It is defined as the rate of motion in distance per unit of time. Mathematically speed or velocity $v$ is given by

$$
v=\mathrm{d} / \mathrm{t}
$$

where, $v$ is the speed of the vehicle in $\mathrm{m} / \mathrm{s}, d$ is distance traveled in m in time $t$ seconds. Speed of different vehicles will vary with respect to time and space. To represent these variation, several types of speed can be defined. Important among them are spot speed, running speed, journey speed, time mean speed and space mean speed.

### 3.2. Analysis of Vehicular Speeds

The average values for the free-flow speeds, speeds during peak hour traffic and operating speeds. Free-flow speed is an important characteristic which affects the capacity, service flow rate, service volumes and daily service volumes. Free-flow speeds were determined separately for the pedestrian cross flow and ideal location. It was seen that the average free flow speeds were almost similar for ideal and pedestrian cross flow location for the site at Medchal .

### 3.3. Speed prediction models

Multiple linear regression models were developed for individual as well as combined side friction parameters for speed prediction. Frictional parameters discussed in previous section were considered as the independent variable while the dependent variable chosen was the average speed ( $\mathrm{m} / \mathrm{s}$ ) of the traffic flow.

$$
\left[Y=a_{0}+a_{1} X_{1}+a_{2} X_{2}+a_{3} X_{3}+a_{4} X_{4}+a_{5} X_{5}+a_{6} X_{6}+a_{7} X_{7}+a_{8} X_{8} \ldots \ldots \ldots \ldots a_{n} X_{n}\right]
$$

## For Speed of 2W:-

$V_{2 w}=2.988+0.493 x_{3 w}+0.561 x_{4 w}+0.114 x_{h v}-0.010 x_{p e d}-0.009 x_{2 w-f l w}-0.004 x_{3 w-f l w}+0.008 x_{4 w-f l w}+0.023 x_{h v-f l w} \quad$ ( $\left.R^{2}=0.91\right)$

$$
(4.148) \quad(3.366) \quad(0.743) \quad(0.975) \quad(1.252) \quad(0.149) \quad(0.905)
$$

For Speed of $\mathbf{3 W}$ :-
$V_{3 w}=2.508+0.390 x_{2 w}+0.452 x_{4 w}-0.071 x_{h v}-0.015 x_{p e d}-0.009 x_{2 w-f l w}-0.004 x_{3 w-f l w}+0.008 x_{4 w-f l w}+0.023 x_{h v-f l w} \quad$ ( $\left.R^{2}=0.90\right)$
(4.148) (3.265) (-0.520) (-1.586) (0.937) (1.673) (0.125) (1.008)

For Speed of 4W:-
$V_{4 w}=-2.686+0.280 x_{2 w}+0.285 x_{3 w}+0.509 x_{h v}+0.009 x_{p e d}+0.009 x_{2 w-f l w}+0.004 x_{3 w-f l w}-0.005 x_{4 w-f l w}-0.007 x_{h v-f l w} \quad$ ( $\left.R^{2}=0.93\right)$
(3.666) (3.265) (5.548) (1.152) (1.838) (0.239) (0.719) (0.506)

For Speed of HV :-
$V_{H V}=3.138+0.066 x_{2 w}-0.052 x_{3 w}+0.588 x_{4 w}-0.023 x_{\text {ped }}-0.009 x_{2 w-f l w}-0.007 x_{3 w-f l w}-0.002 x_{4 w-f l w}+0.018 x_{\text {hv-flw }} \quad$ ( $\mathbf{R}^{2}=0.88$ ) (0.743) (0.520) (5.548) (2.901) (1.667) (0.366) (0.290) (1.163)

Where,

- $y=$ dependent variable
- $\quad x$ values = independent variables
- $\quad$ Vped $=$ speed $(\mathrm{m} / \mathrm{s})$ for pedestrian movement
- $\mathrm{X}_{2 \mathrm{~W}}=$ Speed of 2 Wheelers in $\mathrm{m} / \mathrm{s}$
- $\mathrm{X}_{3 \mathrm{w}}=$ Speed of 3 Wheelers in $\mathrm{m} / \mathrm{s}$
- $X_{4 w}=$ Speed of 4 wheelers in $m / s$
- $X_{h v}=$ Speed of heavy vehicles in $m / s$
- $X_{\text {ped }}=$ Number of pedestrian movement in 5 mins of interval
- $\mathrm{X}_{2 \mathrm{w} \text { Flow }}=$ Number of 2 wheelers in 5 mins of interval
- $X_{3 w}$ Flow $=$ Number of 3 wheelers in 5 mins of interval
- $X_{4 w}$ Flow $=$ Number of 4 wheelers in 5 mins of interval
- $\quad X_{\text {hv Flow }}=$ Number of heavy vehicles in 5 mins of interval

## 4. Capacity

Capacity of a transport facility is defined as the maximum number of vehicles, passengers, or the like, per unit time which can be accommodated under given conditions with a reasonable expectation of occurrence. The Highway Capacity Manual(2010) defines the capacity as the maximum howdy rate at which persons or vehicles can be reasonably expected to traverse a point or a uniform segment of a lane or roadway during a given time period, under prevailing roadway, traffic and control conditions. Several observations can be made from the above definition. Although capacity is the maximum howdy rate, in many situations the break 5 minute flow rate is expressed as the capacity. The above definition also contains the term "reasonably expected" to account for the variation in traffic and driving habit at various location. However, it can be termed as a probabilistic measure. Further, analytical derivations are possible for getting the maximum flow rate, seldom it is achieved in the field. However, capacity measures are often empirically derived. Capacity is usually defined for a point or a uniform segment where operating conditions do not vary. The capacity measure depends on these operating conditions. The first is the traffic conditions and the factors that influence the capacity includes vehicle composition, turning, movements, etc. The second factor is the roadway conditions and it includes geometrical characteristics such as lane width, shoulder width, horizontal alignment, vertical alignment. The third factor is the control conditions such as the traffic signal timings, round-about characteristics.

Table 3 Capacity and Recommended Design Service Volume of Base Section of Urban Roads

| S.No | Typology of the Road | Capacity (PCUs/hr) | Lane Capacity (PCUs/hr) | Design Service Volume(PCUs/hr) |
| :--- | :--- | :--- | :--- | :--- |
| 1 | Two-Lane Undivided | 2400 | 1200 | 1680 |
| 2 | Four-Lane Divided | $5400(2700)$ | 1350 | $3780(1890)$ |
| 3 | Six-Lane Divided | $8400(4200)$ | 1400 | $5880(2940)$ |
| 4 | Eight-Lane Divided | $13600(6800)$ | 1700 | $9520(4760)$ |
| 5 | Ten-Lane Divided | $20000(10000)$ | 2000 | $14000(7000)$ |

### 4.1. Capacity Analysis

Figure 1 Speed Vs Density At Medchal Road
Different models like Greenshield, Greenberg and Underwood model was tried to developed speed flow curves for determination of Capacity. Through the data analysis it was found that Underwood model worked very well as it has higher $\mathrm{R}^{2}$ value of 0.8331 when compared with other two models.

Figure 2 Speed Vs Density Graph Plot At Medchal Road

The capacity value obtained from the speed flow curve is $2998.98 \mathrm{PCU} / \mathrm{sec}$ from the field data.
From the analysis we observed the reduction in capacity on the medchal four lane divided is found to be decreased by 13.08449 \%

So, Reduction in Capacity is $=13.08449 \%$

### 4.2. Level of service

Level-of-Service(LOS) of a traffic facility is a concept introduced to relate the quality of traffic service to a given flow rate. Level-of-Service is introduced by HCM to denote the level of quality one can derive from a local under different operation characteristics and traffic volume. HCM proposes LOS as a letter that designate a range of operating conditions on a particular type of facility. Six LOS letters are defined by HCM, namely A, B, C, D, E, and F, where A denote the best quality of service and $F$ denote the worst. These definitions are based on Measures of Effectiveness (MoE) of that facility. Typical measure of effectiveness include speed, travel-time, density, delay etc. There will be an associated service volume for each of the LOS levels. A service volume or service flow rate is the maximum number of vehicles, passengers, or the like, which can be accommodated by a given facility or system under given conditions at a given LOS.

Level of service is defined as a quantitative measure describing operational conditions. An analysis is done in order to determine the change in level of service of urban roads with increase in pedestrian traffic in combination with varying vehicular traffic. LOS is found out by taking the average travel speed of vehicles as percentage of free flow speed. The standards for choosing the LOS is based on IRC 106-1990. The average speed corresponding to each traffic volume range is found out for different pedestrian volume. This speed is expressed as a percentage of free flow speed of the ideal locations.

Table 4 LOS of multilane divided urban roads based on stream speed, V/C Ratio And FFS

| LOS | Volume/Capacity Ratio | Percentage of Free Flow Speed |
| :--- | :--- | :--- |
| LOS A | $\leq 0.15$ | $\geq 84$ |
| LOS B | $0.15-0.45$ | $83-76$ |
| LOS C | $0.46-0.75$ | $75-59$ |
| LOS D | $0.76-0.85$ | $58-41$ |
| LOS E | $0.86-1.00$ | $40-22$ |
| LOS F | $>1.00$ | $<22$ |

From the detail analysis we have done we obtained maximum speed of vehicle on the medchal four lane divided road.
Highest speed found is $=12.17 \mathrm{~m} / \mathrm{s}(43.18 \mathrm{~km} / \mathrm{hr})$
Which comes under LOS D. This LOS D is mostly approaching unstable flow. Speeds slightly decrease as traffic volume slightly increases. Freedom to maneuver within the traffic stream is much more limited and driver comfort levels decrease

## 5. Conclusion

Study was conducted to analyze in detail the impact of pedestrian movements on speed of four lane divided urban roads in developing countries. Analyses were conducted on speed variability observed on stretches with pedestrian movement.

- Speed prediction models were developed on pedestrian movement parameters and traffic composition. These models were found to be statistically sound, can be used for predicting speeds and therefore speed reduction caused by pedestrian movement.
- All the frictional parameters considered were found to significantly contribute, but negatively to speed which is logically correct. The frictional parameter considered includes the number of pedestrians walking along sides of carriage ways in case of pedestrian dense zones.
- Speed prediction models were employed to assess the impact of variations in pedestrian movements. Speed prediction models developed in the study can be used to determine the speed of traffic flow which is affected by pedestrian crossings.
- Thus, it is recommended that while planning urban road facilities, pedestrian crossings should be given due importance and placed accordingly so that its impact does not affect the traffic flow to a higher level there by reducing the speed of traffic flow.
- The base capacity for a four lane divided urban arterials from Indo HCM Manual is $3450 \mathrm{PCU} / \mathrm{sec}$. Through the development of speed flow curves for Medchal road was 2998.98 PCU/sec. The reduction in capacity due to a bus stop was found to be 13 percent due to the pedestrians movement on the urban roads.
- Urban roads are usually designed for LOS C (IRC:106-1990). But because of pedestrian movement on the road, the level of service got worsen to LOS D, thus causing congestion and travel time delays.

The developed model can be used by the practicing engineers to estimate capacity of the section for any levels of pedestrian movement in traffic stream and subsequently planned the urban roadway policy and design.

## Compliance with ethical standards

## Acknowledgments

We express our thanks to Ch. Gopal Reddy, Secretary, CMRGI, Major .Dr. V.A Narayana, Principal and Dr. A. Krishna Rao HOD, Mr. S. Ghanshyam Singh assistant professor CMR College of Engineering and Technology Hyderabad, for help and encouragement to publish this paper.

## Disclosure of conflict of interest

The authors declare that they have no conflict of interest.
